

[Tutorial] Apache ZooKeeper – Setting ACL in ZooKeeper Client

Posted on [July 24, 2014](#) by [ihong5](#) • Tagged [ZooKeeper](#), [zookeeper acl](#) • [6 Comments](#)

Now let's talk about setting the ACL of a znode in ZooKeeper. Before getting into the details, let's talk more about the scheme and ID.

1. Scheme and ID

ID, as name suggests, is an identifier comprised of a username and password. By default, when the znode has an ACL set accessible by a specific group of users or an individual, the `<username>:<password>` is first hashed using an SHA-1 hashing algorithm, and then it (hex-string) is base-64 encoded.

As mentioned in earlier blog entries, scheme is like a group of users that are authorized to access a certain znode with a scheme-and-id-specific ACL set.

1.1. World Scheme

World scheme has one ID (anyone). This represents any user in the world.

For example, we type in the following command to set the znode accessible by anyone.

```
setAcl /newznode world:anyone:crdwa
```

By doing it correctly, You should get something like this in return:

```
[zk: localhost(CONNECTED) 25] setAcl /newnode world:anyone:crdwa
cZxid = 0x50
ctime = Thu Jul 24 14:19:31 EDT 2014
mZxid = 0x50
mtime = Thu Jul 24 14:19:31 EDT 2014
pZxid = 0x50
cversion = 0
dataVersion = 0
aclVersion = 5
ephemeralOwner = 0x0
dataLength = 7
numChildren = 0
[zk: localhost(CONNECTED) 26] getAcl /newnode
'world,'anyone
: cdrwa
[zk: localhost(CONNECTED) 27]
```

1.2. Auth Scheme

Auth scheme represents a *"manually"* set group of authenticated users. According to the ZooKeeper documentation

(<http://zookeeper.apache.org/doc/r3.1.2/zookeeperProgrammers.html>), auth does not utilize any ID. Unless I am mistaken, this seems not to be the case. Because if you try to set ACL on a znode using auth scheme and not provide any ID, it tells you that is not a valid ID, or some form of ID is needed. Below is a **(bad)** example:

```
setAcl /newznode auth:crdwa
```

as seen above, I did not provide any form of ID. This is what I get:

```
[zk: localhost(CONNECTED) 84] setAcl /newznode auth:crdwa
auth:crdwa does not have the form scheme:id:perm
Acl is not valid : /newznode
[zk: localhost(CONNECTED) 85]
```

A correct way to use this scheme would be as follows:

```
setAcl /newznode auth:username:password:crdwa
```

Using auth scheme allows us to have multiple authorized users to access a single znode with the different username and password combination. Say we have 3 users:

username : password

user_123 : pwd_123

user_456 : pwd_456

user_789 : pwd_789

We can use the same syntax above by replacing username with user_123, user_456, or user_789 and password with pwd_123, pwd_456, or pwd_789 respectively.

1.2.1 addauth Command

One important thing to note is you must use the addauth command **before** proceeding to set the ACL of a znode using the auth scheme. If you try to set the ACL **before** executing the addauth command, you will get an error as below:

```
WatchedEvent state:SyncConnected type:None path:null
[zk: localhost:2181(CONNECTED) 0] ls /
[newnode, newznode, zookeeper]
[zk: localhost:2181(CONNECTED) 1] setAcl /newnode auth:user_123:pwd_123:crdwa
Acl is not valid : /newnode
[zk: localhost:2181(CONNECTED) 2] _
```

Correct way to do is to execute addauth command first, and then execute the setAcl command. Below is the syntax of command execution for addauth:

```
addauth /<node-name> digest <username>:<password>
```

By adding the authenticator and setting ACL accordingly, you can ensure that you set the ACL correctly.

```
[zk: localhost(CONNECTED) 6] addauth digest user_123:pwd_123
[zk: localhost(CONNECTED) 7] setAcl /newnode auth:user_123:pwd_123:cdwa
cZxid = 0x50
ctime = Thu Jul 24 14:19:31 EDT 2014
mZxid = 0x50
mtime = Thu Jul 24 14:19:31 EDT 2014
pZxid = 0x50
cversion = 0
dataVersion = 0
aclVersion = 1
ephemeralOwner = 0x0
dataLength = 7
numChildren = 0
[zk: localhost(CONNECTED) 8] getAcl /newnode
'digest,'user_123:mh/MD3lrRTC1THcHDpfSgpdYoPE=
: cdrwa
[zk: localhost(CONNECTED) 9]
```

Repeat the steps for additional username and password combo, and the ACL for that newznode looks like this:

```
[zk: localhost(CONNECTED) 13] getAcl /newnode
'digest,'user_123:mh/MD3lrRTC1THcHDpfSgpdYoPE=
: cdrwa
'digest,'user_456:EINEyxG7hM0ouxFxeP7U/B3drgo=
: cdrwa
'digest,'user_789:JKb5fGeoKYiNH8qQ/976Rfwni9U=
: cdrwa
[zk: localhost(CONNECTED) 14] _
```

1.3. Digest Scheme

Digest scheme represents an individual user with authentication. This uses username:password string that is hashed using the SHA-1 hashing algorithm, and that hashed string is in turn base64 encoded. According to the ZooKeeper website, it is stated that the MD5 hash of <username>:<password> is used as an ACL ID identity. Unless I am mistaken, that seems not to be the case. Instead, what I found was that <username>:<Base64 encoded SHA-1

hash of username:password> is used as an ACL ID (Please see above pictures under the Auth section).

What's really funny is that if I authenticate an individual user on a znode using digest scheme on ZooKeeper client, instead of storing the username and encoded hash string of <username:password> like it should, it stores a clear, human-readable text of <username:password> as an ID. Executing the addauth command before setting the ACL with digest scheme does not work either. Below is the picture that illustrates my point:

```
[zk: localhost(CONNECTED) 26] getAcl /newnode
'world,'anyone
: cdrwa
[zk: localhost(CONNECTED) 27] addauth digest user_abc:pwd_abc
[zk: localhost(CONNECTED) 28] setAcl /newnode digest:user_abc:pwd_abc:cdrwa
cZxid = 0x50
ctime = Thu Jul 24 14:19:31 EDT 2014
mZxid = 0x50
mtime = Thu Jul 24 14:19:31 EDT 2014
pZxid = 0x50
cversion = 0
dataVersion = 0
aclVersion = 6
ephemeralOwner = 0x0
dataLength = 7
numChildren = 0
[zk: localhost(CONNECTED) 29] getAcl /newnode
'digest,'user_abc:pwd_abc
: cdrwa
[zk: localhost(CONNECTED) 30] _
```

Unless it is easy to work backwards – decoding the user_abc:pwd_abc, and then take that decoded string and undo the SHA-1 hashing part, it turns out setting ACL using digest scheme on a znode in ZooKeeper client is pointless.

Good thing is that if you setAcl a znode using digest scheme via client, you can delete it.

1.4. Host Scheme

Host scheme represents anyone within the same hosting server. I have not done enough with the host scheme yet, but I will come back to this with more details.

1.5. IP Scheme

IP scheme represents any user within the same IP address. Easiest example to use in this case would be `127.0.0.1`, which represents the user of that any local machine, since any local machine will have `127.0.0.1` point to the `localhost`. Below is the syntax of `setAcl` using IP scheme:

```
setAcl /<node-name> ip:<IPv4-address>:<permission-set>
```

Using the syntax above, below is an example using the `127.0.0.1` IP address:

```
setAcl /newnode ip:127.0.0.1:crdwa
```

If done correctly, you should get the znode stat like the picture below:

```
[zk: localhost(CONNECTED) 35] setAcl /newnode ip:127.0.0.1:crdwa  
cZxid = 0x60  
ctime = Thu Jul 24 16:35:31 EDT 2014  
mZxid = 0x60  
mtime = Thu Jul 24 16:35:31 EDT 2014  
pZxid = 0x60  
cversion = 0  
dataVersion = 0  
aclVersion = 1  
ephemeralOwner = 0x0  
dataLength = 7  
numChildren = 0  
[zk: localhost(CONNECTED) 36]
```

That is it for now. On my next blog post, I will briefly talk about how to access them in Java; furthermore, I will talk more in detail about how username and password are stored. Thanks for reading as usual, and happy zookeeping!

You post interesting articles here. Your page deserves much bigger audience.
It can go viral if you give it initial boost, i know very
useful service that can help you, simply type in google: svetsern traffic tips

Thanks a lot ☐ The official documentation is also not helping much. This post is the best I found in the internet.

I realize this is ancient, but I found this in a google search and was briefly led astray, so I wanted to be a good citizen and clear up an

error here!

> What's really funny is that if I authenticate an individual user on a znode using digest scheme on ZooKeeper client, instead of storing the username and encoded hash string of like it should, it stores a clear, human-readable text of as an ID.

When you auth, you want to send "digest", "username:password". When you set an ACL, you're responsible for running the sha1 operation yourself- In fact, in your example, if instead of getAcl /newNode you attempted to do get /newNode, it would fail!

Instead, you would need to run an operation like this:

```
{hash} = b64encode(sha1(user_abc:pwd_abc))  
setAcl /newnode digest:user_abc:{hash}:crdwa
```

As a result, getAcl will not show the password in cleartext, but a user who authenticates as user_abc:pwd_abc will be able to operate against the node.

The kazoo source is a good reference for how this is supposed to work. Enjoy!

How can I change the scheme or auth or acl in a znode??
